Consider the following class for tree nodes in the given tree.

```
1 class Node:
2     def __init__(self, value = None):
3         self.value = value
4         self.left = None
5         self.right = None
```

```
1 def traversal(t):
2     if t != None:
3         traversal(t.left)
4         traversal(t.right)
5         print(t.value, end = ' ')
6 traversal(root) # 'root' is the reference of the root node of the given tree.
```

Which of the following order will be printed by the given code-snippet?

Which of the following statement(s) is/are **true**?

Options :

6406531165958. ✓ Given a graph where all edges have positive weights, the shortest path produced by Dijkstra's and Bellman-Ford algorithm may be different, but the path weight would be the same.

6406531165959. ✗ Given a graph where weights of all edges are unique, there is always a unique shortest path from a source to destination in such a graph.

6406531165960. ✓ Bellman-Ford and Floyd-Warshall's algorithm can calculate the shortest path correctly if the graph has negative edge weights but does not have negative weight cycles.

6406531165961. ✗ The time complexity of Floyd-Warshall is $O(V^2)$, where V is the number of vertices in the graph.

Allowed : No **Group Comprehension Questions :** No **Calculator :** None **Response Time :** N.A

Think Time : N.A **Minimum Instruction Time :** 0

Question Numbers : (96 to 97)

Question Label : Comprehension

Consider the following function that takes a list `L` of distinct integers and an integer `k` ($1 \leq k \leq \text{len}(L)$) as input.

```
1 #lower and upper argument represent lower index and upper index of L
  respectively
2 def mystery(L, lower, upper, k):
3     if (k > 0 and k <= upper - lower + 1):
4         pos = partition(L, lower, upper)
5         if (pos - lower == k - 1):
6             return L[pos]
7         if (pos - lower > k - 1):
8             return mystery(L, lower, pos - 1, k)
9         else:
10            return mystery(L, pos + 1, upper, k - pos + lower - 1)
```

In line 3, `partition` function treats the first element of `L` as a pivot and rearranges the list so that all elements less than or equal to the pivot are in the left part of the list, and all elements greater than the pivot are in the right part. In addition, it moves the pivot so that the pivot is the last element of the left part. The function returns the index of pivot in the list `L`.

Based on the above data, answer the given subquestions.
